REMARKS

By this Amendment, claims 1-14 are amended. Thus, claims 1-14 are active in the application. Reexamination and reconsideration of the application are respectfully requested.

The specification and abstract have been carefully reviewed and revised in order to correct grammatical and idiomatic errors in order to aid the Examiner in further consideration of the application. The amendments to the specification and abstract are incorporated in the attached substitute specification and abstract. No new matter has been added.

Also attached hereto is a marked-up version of the substitute specification and abstract illustrating the changes made to the original specification and abstract.

In item 3 on page 2 of the Office Action, claims 9 and 10 were rejected under 35 U.S.C. § 112, first paragraph, as failing to comply with the written description requirement. In particular, the Examiner asserted that the limitation “wherein the magnetic force of the second magnet portion is greater than that of the first magnetic portion” in claim 9 and the limitation “wherein the magnetic force of the second magnet portion is twice that of the first magnetic portion” in claim 10 are inconsistent with the description of lines 1-4 on page 21 of the original specification (corresponding to lines 1-5 on page 21 of the substitute specification).

Lines 1-4 on page 21 of the original specification provide that the inventors of the present application have experimentally found that in order to stably rotate the ball 21, the magnetic force of the fifth fixed magnetic member 35 should be twice the magnet force of each of the first to fourth fixed magnetic members 31 to 34.

In view of this disclosure of the specification, claim 9 has been amended to clarify that “the magnetic force of said second magnet portion is greater than that of each magnet in said first magnet portion.” Claim 10 has also been amended to clarify that “the magnetic force of said second magnet portion is twice that of each magnet in said first magnet portion.”

Accordingly, the Applicants respectfully submit that amended claims 9 and 10 are clearly consistent with the disclosure of the specification. Consequently, the inventions

of claims 9 and 10 comply with the written description and enablement requirements of 35 U.S.C. § 112, first paragraph.

Therefore, the Applicants respectfully request the Examiner to withdraw the rejection of claims 9 and 10 under 35 U.S.C. § 112, first paragraph.

Support for the amendments made to claim 3 can be found in lines 1-3 and 18-22 on page 15 of the original and substitute specifications.

In item 5 on page 3 of the Office Action, claims 1-6 and 9-12 were rejected under 35 U.S.C. § 103(a) as being unpatentable over Keiji et al. (JP 2002-140160, hereinafter “Keiji”) in view of Hiroaki et al. (JP 09-282088, hereinafter “Hiroaki”). This rejection is respectfully traversed for the following reasons.

The present invention provides a trackball for inputting operation information to electronic devices. To overcome the deficiencies with conventional trackballs, the trackball of the present invention provides a stable crisp click without rotational play to the user while the user is performing an operation of rotating the ball of the trackball. Furthermore, the trackball of the present invention provides stable operability even in an environment in a vehicle where vibration and movement are present.

The trackball of the present invention comprises a ball portion magnetically coupleable in directions of a first axis and a second axis, where the first and second axes intersect each other at the center of the ball portion are orthogonal to each other, and a case portion for enclosing the ball portion such that an upper portion of the ball portion is exposed.

To achieve the above-described features of providing a stable crisp click without rotational play to a user while the user is performing an operation of rotating the ball of the trackball, even in a vehicle where vibration and movement are present, the trackball comprises a novel and advantageous arrangement of a first magnet portion and a second magnet portion.

The first magnet portion stabilizes the ball portion at predetermined rotation angles by magnetically coupling to the ball portion in one of the axial directions. The second magnet portion attracts the ball portion in a direction orthogonal to a rotation axis of the ball portion, by magnetically coupling to the ball portion in the other one of the axial directions.

Claim 1 recites the above-described features of the trackball of the present invention.

As acknowledged by the Examiner, Keiji fails to disclose or suggest a trackball which comprises a second magnet portion for attracting the ball portion in a direction orthogonal to a rotation axis of the ball portion, by magnetically coupling to the ball portion in the other one of the axial directions, as recited in claim 1.

In an attempt to teach this feature, the Examiner applied Hiroaki, which discloses the use of a permanent magnet 31 to provide a crisp click by producing attraction and repulsion on a ball portion. That is, the permanent magnet 31 in Hiroaki provides the crisp click by producing the attraction and repulsion on the ball portion. However, the permanent magnet 31 does not provide a stable crisp click to a user.

Accordingly, one skilled in the art would clearly not combine the permanent magnet 31 of Hiroaki with Keiji to result in the trackball recited in claim 1, because it would not be possible to modify Keiji to include the permanent magnet 31 of Hiroaki to result in a trackball that provides a stable crisp click without rotational play to a user while the user is performing an operation of rotating the ball of the trackball.

Moreover, a repulsion accrues between the permanent magnet 31 and the ball portion of Hiroaki. Consequently, the repulsion caused by the permanent magnet 31 of Hiroaki makes rotation of the ball portion unstable and therefore makes a crisp click unstable.

Therefore, if one skilled in the art tries to obtain a stable crisp click based on the inventions of Keiji and Hiroaki, it would not be possible to do so, because the permanent magnet 31 of Hiroaki makes rotation of the ball portion unstable.

Accordingly, in contrast to the Examiner's assertion, the Applicants respectfully submit that Hiroaki does not cure the deficiencies of Keiji, because the repulsion caused by the permanent magnet 31 prevents construction of a second magnet portion for attracting the ball portion in a direction orthogonal to a rotation axis of the ball portion, by magnetically coupling to the ball portion in the other one of the axial directions, as recited in claim 1.

Therefore, no obvious combination of Keiji and Hiroaki would result in the invention of the trackball of claim 1, since Keiji and Hiroaki, either individually or in

combination, clearly fail to disclose or suggest the second magnet portion as well as the novel effects produced by the trackball of claim 1.

Accordingly, the Applicants respectfully submit that claim 1 is clearly patentable over the combination of Keiji and Hiroaki.

Notwithstanding the clear patentability of claim 1 over Keiji and Hiroaki, the Applicants respectfully submit that the combination of Keiji and Hiroaki also do not result in the inventions of claims 3 and 5.

Claim 3 recites that the first magnet portion comprises a first fixed magnet portion made up of a pair of first magnets for forming a first rotation axis by magnetically coupling to a first bar member, which is arranged on the first axis and made of an unmagnetized material. Claim 3 also recites that the first magnet portion comprises a second fixed magnet portion made up of a pair of second magnets for forming a second rotation axis by magnetically coupling to the third bar member, which is arranged on a third axis intersecting with the first and second axes at the center of the ball portion and orthogonal to the first and second axis and which is also made of an unmagnetized magnetic material. The first magnets of the first fixed magnet portion and the second magnets of the second fixed magnet portion are recited as being respectively fixed to side-surfaces of the case portion.

Claim 3 defines that the second magnet portion comprises a third fixed magnet portion for attracting the second bar member by magnetically coupling to the second bar member, where the third fixed magnet portion is fixed to a bottom-surface of the case portion.

Lines 1-3 on page 15 of the original and substitute specifications provide that “[t]he first to fourth fixed magnetic members 31 to 34 all have the same pole (e.g., north pole) directed toward the center of the ball 21, and are magnetized to have the substantially the same charge.” Furthermore, lines 18-22 on page 15 of the original and substitute specifications provide that “[t]he fifth fixed magnetic member 35 has a pole opposite (e.g., south pole) to that of the first to fourth fixed magnetic members 31 to 34 directed toward the center of the ball 21,” and is magnetized to have a magnetic charge about twice the magnetic charge of the first to fourth fixed magnetic members 31 to 34.

Claim 3 recites this feature of the present invention. In particular, claim 3 recites that the first and second fixed magnet portions each have a common pole directed toward a center of the ball portion, and that the third fixed magnet portion has a pole opposite to that of the first and second fixed magnet portions directed toward the center of the ball portion.

Neither Keiji nor Hiroaki disclose, suggest or even contemplate this feature of the present invention.

Therefore, in addition to the clear patentability of claim 1 over Keiji and Hiroaki, claim 3 is also clearly patentable over Keiji and Hiroaki.

Another novel feature of the present invention is recited in claim 5. In particular, claim 5 recites that the case portion is made of an unmagnetized magnetic material.

Owing to this feature, a magnetic circuit such as magnetic fluxes forms a loop comprising N of the first magnet portion → S of the second magnet portion → N of the second magnet portion → S of the first magnet portion. As a result, the magnetic force increases and leakage magnetic fluxes can be reduced. Owing to the increased magnetic force, a more assured crisp click can be provided to a user and the rotation of the ball portion can be made more stable (see paragraph [0036] in lines 3-15 on page 16 of the original specification, in lines 4-16 on page 16 of the substitute specification, and Figure 6).

On the other hand, Hiroaki discloses that on a surface of a trackball, a N pole and a S pole are alternately magnetized and a magnetic force does not form a loop.

Furthermore, as acknowledged by the Examiner, Keiji does not even contemplate using an unmagnetized magnetic material for its case portion, and therefore, cannot obtain the novel effects of the invention of claim 5 as described above.

Therefore, in addition to the clear patentability of claim 1 over Keiji and Hiroaki, claim 5 is also clearly patentable over Keiji and Hiroaki.

In item 7 on page 9 of the Office Action, claims 13 and 14 were rejected under 35 U.S.C. § 103(a) as being unpatentable over Keiji in view of Hiroaki and further in view of Lachman (U.S. 5,021,771).

Independent claim 13 recites an in-vehicle device controller which comprises a trackball for inputting operation information to electronic devices mounted on a vehicle.

The in-vehicle device of claim 13 comprises the trackball as recited in independent claim 1.

As demonstrated above, neither Keiji nor Hiroaki disclose or suggest each and every feature of the trackball recited in claim 1. Namely, the combination of Keiji and Hiroaki clearly fails to disclose or suggest the second magnet portion of the trackball of claim 1 as well as the effects of providing a stable crisp click without rotational play to a user while the user is performing an operation of rotating the ball of the trackball.

Lachman, however, was only applied because the combination of Keiji and Hiroaki fail to contemplate a trackball being mounted on a steering wheel portion of a vehicle. Lachman discloses a graphical input sphere (trackball) 55 which is mounted on a spoke 54 of a steering wheel 50 to permit the driver to use his thumb to control a display device (see Column 6, lines 43-54 and Figure 4).

Nevertheless, similar to Keiji and Hiroaki, Lachman also fails to disclose or suggest a trackball comprising the second magnet portion recited in claim 1 or the effects of the trackball of providing a stable crisp click without rotational play to a user while the user is performing an operation of rotating the ball of the trackball.

Consequently, Lachman does not cure the deficiencies of Keiji and Hiroaki for failing to disclose or suggest each and every limitation of the trackball recited in claims 1 and 13.

Therefore, no obvious combination of Keiji, Hiroaki and Lachman would result in the inventions of claims 1 and 13 since Keiji, Hiroaki and Lachman, either individually or in combination, clearly fail to disclose or suggest each and every limitation of the trackball recited in claims 1 and 13.

Accordingly, claims 1 and 13, as well as claims 2-12 and 14 which depend therefrom, are clearly patentable over any obvious combination of Keiji, Hiroaki and Lachman.

In item 6 on page 9 of the Office Action, dependent claims 7 and 8 were rejected under 35 U.S.C. § 103(a) as being unpatentable over Keiji in view of Hiroaki and further in view of Kermani et al. (U.S. 6,504,528, hereinafter “Kermani”).

As demonstrated above, Keiji and Hiroaki clearly fail to disclose or suggest a trackball comprising the second magnet portion recited in claim 1 or the effects of the

trackball of providing a stable crisp click without rotational play to a user while the user is performing an operation of rotating the ball of the trackball.

Similar to Keiji, Hiroaki and Kermani also fails to disclose or suggest a trackball comprising the second magnet portion of claim 1 or the effects obtained by the trackball of claim 1.

Consequently, Kermani does not cure the deficiencies of Keiji and Kermani for failing to disclose or suggest each and every feature of the trackball recited in claim 1, as well as the trackball recited in claim 13.

Therefore, no obvious combination of Keiji, Hiroaki and Kermani would result in the invention of claims 1 and 13 since Keiji, Hiroaki and Kermani, either individually or in combination, clearly fail to disclose or suggest each and every limitation of claims 1 and 13.

Accordingly, claim 1, as well as claims 2-12 which depend therefrom, are clearly patentable over any obvious combination of Keiji, Hiroaki and Kermani.

As demonstrated above, Keiji, Hiroaki, Lachman and Kermani, either individually or in combination, clearly fail to disclose or suggest each and every feature of the trackball recited in claims 1 and 13.

Furthermore, it is submitted that the clear distinctions between the inventions of claims 1 and 13 and Keiji, Hiroaki, Lachman and Kermani are such that a person having ordinary skill in the art at the time the invention was made would not have been motivated to modify Keiji, Hiroaki, Lachman and Kermani in such a manner as to result in, or otherwise render obvious, the present invention as recited in claims 1 and 13.

Therefore, it is submitted that the claims 1 and 13, as well as claims 2-12 and 14 which depend therefrom, are clearly allowable over the prior art as applied by the Examiner.

In view of the foregoing amendments and remarks, it is respectfully submitted that the present application is clearly in condition for allowance. An early notice thereof is respectfully solicited.

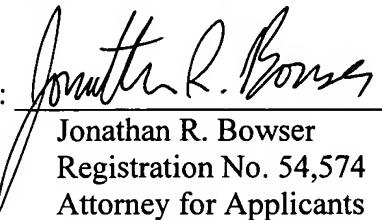

If, after reviewing this Amendment, the Examiner feels there are any issues remaining which must be resolved before the application can be passed to issue, the

Examiner is respectfully requested to contact the undersigned by telephone in order to resolve such issues.

A fee and a Petition for a one-month Extension of Time are filed herewith pursuant to 37 CFR § 1.136(a).

Respectfully submitted,

Atsushi IISAKA et al.

TITLE OF THE INVENTION

TRACKBALL AND IN-VEHICLE DEVICE CONTROLLER USING THE
TRACKBALL

5 BACKGROUND OF THE INVENTION

1. Field of the Invention

[0001] The present invention relates to a trackball used for controlling electronic devices and an in-vehicle device controller using the trackball. More particularly, the present invention 10 relates to a trackball which is capable of providing the user with a feel of rotating a ball included in the trackball and to an in-vehicle device controller using such a trackball.

2. Description of the Background Art

[0002] A trackball is a device used for controlling electronic 15 devices by rotating a ball included in the trackball.

[0003] In cases where a trackball is used to operate a personal computer, it is desirable for the pointer on the PC screen to be able to make minute movements in response to movement of the trackball's ball. Thus, it is preferable that a ball included 20 in such a trackball rotate smoothly ~~rotate without interruption~~ of movement while rotating and without giving the user an awkward feel.

[0004] On the other hand, in cases where a trackball is used to control the set temperature, etc., in an air-conditioning system, 25 the cursor on a control screen only needs to be able to move in

a stepwise manner, and there is no need for the cursor to move smoothly. Therefore, it is preferable that a ball included in such a trackball rotate intermittently in a manner such that the ball rests stably once at a stage where the ball has rotated a 5 predetermined angle to give the user a resistance feel and then again begins rotating as the user applies further force. The feel given to the user when the ball makes such a movement is hereinbelow called a crisp click. The user can, by obtaining a crisp click, intuitively adjust a set temperature, etc., and can obtain a good 10 operational feel.

[0005] Conventionally, trackballs that provide a crisp click have been suggested (see Japanese Laid-Open Patent Publication No. 2002-140160).

[0006] FIG. 20 is a cross-sectional view of a conventional 15 trackball 200 that provides a crisp click. In FIG. 20, the trackball 200 includes a ball 221, a case 222, four fixed magnetic members 231 to 234 (note that the magnetic members 232 and 234 extend in a direction perpendicular to the plane of ~~the figure~~FIG. 20 and thus are shown by a dotted line in FIG. 20), and magnetic 20 sensors 236A, 236B, 237A, and 237B (note that the magnetic sensor 237B is present at the far end along a direction perpendicular to the plane of ~~the figure~~FIG. 20 and thus reference numeral 237B is shown in brackets parentheses in FIG. 20).

[0007] The ball 221 has included therein three bar members 226, 25 227, and 228 arranged on three axes that intersect with one another

at the center of the ball 221 and are orthogonal to one another. The bar members 226, 227, and 228 are made of an unmagnetized magnetic material, such as iron, and are embedded inside the ball 221.

[0008] The case 222 is used to rotatably support the ball 221.

5 The fixed magnetic members 231 to 234 are disposed on the inner surface of the case 22-222 on two axes orthogonal to each other on a horizontal plane penetrating through the center of the ball 221, so as not to contact with the ball 221.

10 [0009] The magnetic sensors 236A and 236B are provided to detect a rotation of the ball 221 in the longitudinal direction. The magnetic sensors 237A and 237B are provided to detect a rotation of the ball 221 in the transverse direction.

15 [0010] Among the three bar members 226, 227, and 228 embedded in the ball 221, any two bar members present on the same plane are attracted by the magnetic force of the fixed magnetic members 231 to 234. Therefore, for example, in a state shown in FIG. 20, by the force with which the fixed magnetic members 231 and 233 attract the bar member 226, a magnetic-force-based rotation axis emerges between the fixed magnetic members 231 and 233. In addition, 20 by the force with which the fixed magnetic members 232 and 234 attract the bar member 227, a magnetic-force-based rotation axis emerges between the fixed magnetic members 232 and 234. Thus, the user can rotate the ball 221 around either of these axes.

25 [0011] For example, when a force is applied to the ball 221 in a Y direction (see the arrow in ~~the figure~~FIG. 20), the ball

221 rotates around the rotation axis connecting between the fixed magnetic members 232 and 234. Here, since the bar member 226 is attracted to the fixed magnetic members 231 and 233, the user feels the magnetic force of the fixed magnetic members 231 and 233 while 5 applying a force to the ball 221. As the rotation of the ball 221 proceeds, the bar member 228 is attracted to the fixed magnetic members 231 and 233. When the ball 221 has been rotated by 90°, the bar member 228 is attracted to the fixed magnetic members 231 and 233. Consequently, the ball 221 stops stably stops. If the 10 ball 221 is further allowed to rotate, the user would feel the magnetic force acting between the bar member 228 and the fixed magnetic members 231 and 233, as a resistance. Accordingly, the user can feel that the ball 221 rotates without play, and can obtain a crisp click every 90° rotation.

15 [0012] In the above-described conventional trackball, however, by the force that the user applies to the ball, the distance between the ball and the fixed magnetic members changes slightly. This causes a great change in the magnetic coupling between the ball and the fixed magnetic members. Hence, when the ball is allowed 20 to rotate, the force of the bar members embedded in the ball and the fixed magnetic members fixed to the case wanting to come into contact with one another acts strongly. As a result, an operational feel given to the user is not always satisfactory.

25 SUMMARY OF THE INVENTION

[0013] Therefore, an object of the present invention is to provide a trackball that provides, in performing an operation of rotating the ball, a stable crisp click without rotational play to the user.

5 [0014] Another object of the present invention is to provide a trackball that provides stable operability even in an environment in a vehicle where vibration and movement are present, and an in-vehicle device controller that assists the user with easy control of devices mounted in a vehicle, such as an air-conditioning
10 system, a navigation system, and an audio system.

[0015] The present invention has the following features to attain the objects mentioned above. A first aspect of the present invention is directed to a trackball for inputting operation information to electronic devices, comprising. The
15 trackball comprises: a ball portion magnetically coupleable in directions of a first axis and a second axis, where the first and second axes intersecting with each other at the center of the ball portion and are orthogonal to each other; a case portion for enclosing the ball portion such that an upper portion of the ball
20 portion is exposed; a first magnet portion for stabilizing the ball portion at predetermined rotation angles by magnetically coupling to the ball portion in one of the axial directions; and a second magnet portion for attracting the ball portion in a direction orthogonal to a rotation axis of the ball portion, by
25 magnetically coupling to the ball portion in the other one of the

axial directions.

[0016] The ball portion may preferably be magnetically coupleable in a direction of a third axis intersecting with the first and second axes at the center of the ball portion and orthogonal to the first and second axes. The first magnet portion may allow each of any two axes among the first to third axes which are present on the same plane to serve as a rotation axis of the ball portion.

[0017] In a preferred embodiment, the ball portion may preferably comprise first to third bar members respectively arranged on the first to third axes ~~respectively~~ and made of an unmagnetized magnetic material. The first magnet portion may comprise: a first fixed magnet portion made up of a pair of magnets for forming a first rotation axis by magnetically coupling to the first bar member, where the magnets ~~being~~are respectively fixed to side-surfaces of the case portion; and a second fixed magnet portion made up of a pair of magnets for forming a second rotation axis by magnetically coupling to the second bar member, where the magnets ~~being~~are respectively fixed to side-surfaces of the case portion. The second magnet portion may comprise a third fixed magnet portion for attracting the third bar member by magnetically coupling to the third bar member, where the third fixed magnet portion ~~being~~is fixed to a bottom-surface of the case portion.

[0018] Furthermore, the ball portion may further comprise an even number of bar members respectively arranged on an even number of axes ~~respectively~~ and made of an unmagnetized magnetic material,

where the even number of axes intersecting at an intersection point of any two axes among the first to third axes which are present on the same plane, and at equal angles.

[0019] The case portion may preferably be made of an
5 unmagnetized magnetic material.

[0020] In another preferred embodiment, the above-described trackball may preferably further comprise a third magnet portion
which is arranged at a location that makes a predetermined angle from any one of rotation axes formed by the first magnet portion,
10 and stabilizing which stabilizes the ball portion by magnetic coupling when the ball portion rotates around ~~the~~ any one of the rotation axes. In this embodiment, the trackball may preferably further comprise means for switching between a presence and absence of a magnetic force of the third magnet portion. The magnetic
15 force switching means may preferably perform the switching in accordance with control parameters of the electronic devices.

[0021] In all of the above-described embodiments, the magnetic force of the second magnet portion may be greater than ~~that~~ the magnetic force of the first magnet portion. Specifically, the
20 magnetic force of the second magnet portion is preferably twice that of the first magnet portion.

[0022] In still another preferred embodiment, the ball portion may be magnetically coupleable in directions of a plurality of axes on a plane made up of the first and second axes, where the
25 plurality of axes intersecting at an intersection point of the

first and second axes. The case portion may expose the upper portion of the ball portion so as to restrict a rotation angle of the ball portion. Specifically, the plurality of axes may be in an even number. The ball portion may comprise: first and

5 second bar members respectively arranged on the first and second axes respectively and made of an unmagnetized magnetic material; and an even number of bar members respectively arranged on the plurality of axes respectively and made of an unmagnetized magnetic material. The first bar member, the second bar member, and the
10 plurality of bar members may be arranged with an equal angle therebetween. The case portion may expose the upper portion of the ball portion such that the ball portion rotates at an angle corresponding to an angle between the bar members.

[0023] A trackball such as that described above may be applied
15 to an in-vehicle device controller for controlling electronic devices mounted on a vehicle. In addition, the trackball may be mounted on a steering wheel of the vehicle.

[0024] These and other objects, features, aspects and advantages of the present invention will become more apparent from
20 the following detailed description of the present invention when taken in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

[0025] FIG. 1 is an external perspective diagram showing a
25 cockpit of a vehicle equipped with a trackball according to

Embodiment 1a first embodiment of the present invention;

FIG. 2 is a schematic diagram showing the external view of an in-vehicle device controller 1 and the configuration of an in-vehicle system to which the in-vehicle device controller 1 is
5 applied;

FIG. 3 is a cross-sectional view of a trackball 2 taken along a YZ plane;

FIG. 4 is a cross-sectional view of the trackball 2 taken along a horizontal center plane A-a shown in FIG. 3, viewed from
10 the direction of the arrow L;

FIG. 5 is a cross-sectional view of the trackball 2 taken along a horizontal center plane B-b shown in FIG. 3, viewed from the direction of the arrow L;

FIG. 6 is a diagram showing a magnetic flux generated
15 by first to fifth fixed magnetic members 31 to 35 and a case 22;

FIG. 7 is a diagram showing a state in which a ball 21 is in the process of rotating;

FIG. 8 is an illustrative diagram showing an application example of the in-vehicle device controller 1 having the trackball
20 2 mounted thereon;

FIG. 9 is an illustrative diagram showing an application example of the in-vehicle device controller 1 having the trackball 2 mounted thereon;

FIG. 10 is an illustrative diagram showing an application
25 example of the in-vehicle device controller 1 having the trackball

2 mounted thereon;

FIG. 11 is a cross-sectional view of a trackball 2a according to ~~Embodiment 2a second embodiment~~ of the present invention;

5 FIG. 12 shows a state in which a ball 21 is rotated 45° from the position shown in FIG. 11 with the central axis of a bar member 27, i.e., the axis formed between fixed magnetic members 32 and 34, as the rotation axis;

10 FIG. 13 is a cross-sectional view of a ball 21 taken along a YZ plane;

FIG. 14 is a diagram showing another configuration example of the ball;

15 FIG. 15 is a cross-sectional view of a trackball 2b taken along a YZ plane, according to ~~Embodiment 3a third embodiment~~ of the present invention;

FIG. 16 is a cross-sectional view of the trackball 2b taken along an XY plane, according to ~~Embodiment 3the third embodiment~~ of the present invention;

20 FIG. 17 is a cross-sectional view of a ball 21a taken along the YZ plane;

FIG. 18 is a diagram showing another configuration example of the ball;

25 FIG. 19 is an external perspective diagram showing a cockpit of a vehicle equipped with a trackball 401 according to ~~Embodiment 4a fourth embodiment~~ of the present invention; and

FIG. 20 is a cross-sectional view of a conventional trackball 200 that provides a crisp click.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

5 **[0026]** {First Embodiment-1}

FIG. 1 is an external perspective diagram showing a cockpit of a vehicle equipped with a trackball according to
Embodiment 1a first embodiment of the present invention. In FIG. 1, the cockpit of the vehicle includes an in-vehicle device controller 1, a trackball 2, and a display 3. The trackball 2 is mounted on the in-vehicle device controller 1. For describing the rotation direction of a ball included in the trackball 2, X, Y, and Z axes are provided in ~~the figure~~FIG. 1 to show directions. It is to be noted that in ~~the figure~~FIG. 1, for clarification, the center of the X, Y, and Z axes is provided away from the trackball 2, but in the following description the center of the X, Y, and Z axes lies in the center of the ball included in the trackball 2. The X axis indicates the left and right direction of the vehicle. The Y axis indicates the forward and backward direction of the vehicle. The Z axis indicates the vertical direction of the vehicle.

[0027] As shown in FIG. 1, the in-vehicle device controller 1 is provided at an extension of the center console of the vehicle between the driver's seat and the front seat. Therefore, a driver or a passenger in the front seat can operate the in-vehicle device

controller 1 by hand. Objects to be controlled by the in-vehicle device controller 1 include electronic devices, such as a navigation system, an audio system, an air-conditioning system, and a TV mounted on a vehicle (hereinafter referred to as in-vehicle devices). The display 3 displays menu screens for controlling various in-vehicle devices.

[0028] FIG. 2 is a schematic diagram showing the external view of the in-vehicle device controller 1 and the configuration of an in-vehicle system to which the in-vehicle device controller 1 is applied. In FIG. 2, for the X, Y, and Z axes, their forward directions are indicated by using arrows (the same applies to the ~~following figures~~remaining drawings). Each in-vehicle device 11 is connected to the in-vehicle device controller 1 by communication means, such as a serial communication. The user can control the in-vehicle device 11 by operating the in-vehicle device controller 1. The in-vehicle device 11 sends information concerning its menu screen to the in-vehicle device controller 1.

[0029] The in-vehicle device controller 1 includes buttons 4 to 8, the trackball 2, and a rest portion 9. The buttons 4 to 8 are provided to select any of the in-vehicle devices 11 to be controlled. The number of buttons 4 to 8 is five to match the number of fingers on one hand. The buttons 4 to 8 are arranged such that the user can press the buttons without looking. The trackball 2 is a device used for controlling the in-vehicle device 11 that has been selected as a control object by any of the buttons

4 to 8. The user controls the in-vehicle device 11 by rotating
a ball 21 of the trackball 2. The rest portion 9 has a shape such
that the operator's hand fits therein so that the portion of the
hand from the wrist to the palm is stably rested when rotating
5 the ball 21, thereby achieving an easy operation of the ball 21.

[0030] Next, with reference to FIGS. 3 to 5, the structure of
the trackball 2 is described. FIG. 3 is a cross-sectional view
of the trackball 2 taken along a YZ plane. FIG. 4 is a
cross-sectional view of the trackball 2 taken along a horizontal
10 center plane A-a shown in FIG. 3, viewed from the direction of
the arrow L. FIG. 5 is a cross-sectional view of the trackball
2 taken along a horizontal center plane B-b shown in FIG. 3, viewed
from the direction of the arrow L.

[0031] The trackball 2 includes a spherical ball 21, a case
15 22 made of iron for enclosing the ball 21, a cover plate 24 for
covering the case 22 such that the upper portion of the ball 21
protrudes from the cover plate 24, first to fourth fixed magnetic
members 31, 32, 33, and 34, rollers 40, 41, and 42, shafts 43,
44, and 45, shaft bearings 46A, 46B, 47A, 47B, 48A, and 48B, and
20 rotary encoders 50 and 51.

[0032] The ball 21 includes a moving-magnet member 25 made of
an unmagnetized, soft magnetic material, and a resin portion 29
made of a non-magnetic material. The moving-magnet member 25 has
three bar members 26, 27, and 28. The bar members 26, 27, and
25 28 are arranged on three axes (X, Y, and Z axes) orthogonal to

one another and are embedded in the resin portion 29. The bar members 26, 27, and 28 each have a length such that both ends thereof are present near the vicinity of the surface of the ball 21. The entire surface of the ball 21 is preferably covered, for example, 5 with a hard and smooth insulating coating. As shown in FIG. 5, the ball 21 is supported by the three rollers 40, 41, and 42 with the lower part from the center of the ball 21 rotatable in all directions. The upper portion of the ball 21 is exposed from a round hole in the center of the cover plate 24.

10 [0033] The rollers 40 and 41 are provided so that their rotation axes are orthogonal to each other. The rollers 40, 41, and 42 are respectively joined to the shafts 43, 44, and 45 penetrating through the center of the rollers such that the rollers do not slide on the respective shafts. The shafts 43, 44, and 45 are 15 rotatably supported by the shaft bearings 46A and 46B, 47A and 47B, and 48A and 48B fixed to the case 22, respectively. To the ~~shafts 43 and 44 are connected the~~ rotary encoders 50 and 51 are connected to the shafts 43 and 44, respectively. The rotary encoders 50 and 51 detect the rotation direction and rotation amount 20 of the rollers 40 and 41, respectively. A detection portion (not shown in the figures) connected to the rotary encoders 50 and 51 detects movement of the ball 21 rotating around the two shafts 43 and 44, based on the rotation direction and rotation amount of the ball 21 obtained from the rotary encoders 50 and 51.

25 [0034] As shown in FIG. 4, the first to fourth fixed magnetic

members 31 to 34 are bonded and fixed to the case 22 so as to be aligned on the X and Y axes of an XY plane that penetrates through the center of the ball 21. A given space is provided between each of the first to fourth fixed magnetic members 31 to 34 and the 5 surface of the ball 21. The first to fourth fixed magnetic members 31 to 34 all have the same pole (e.g., north pole) directed toward the center of the ball 21, and are magnetized to have substantially the same magnetic charge. The first to fourth fixed magnetic members 31 to 34 are to be magnetically coupled to both ends 26A, 10 26B, 27A, 27B, 28A, and 28B of the three bar members 26 to 28 embedded in the ball 21. The first to fourth fixed magnetic members 31 to 34 have a cuboid shape. The first to fourth fixed magnetic members 31 to 34 are made of, for example, a rare-earth magnet which, though small in size, generates a powerful magnetic coupling 15 and is easy to process. The first to fourth fixed magnetic members 31 to 34 all have the same magnetic force.

[0035] As shown in FIG. 3, a fifth fixed magnetic member 35 is bonded and fixed at the center of the bottom part of the case 22, i.e., in the reversed direction of a Z axis penetrating through 20 the center of the ball 21. A given space is provided between the fifth fixed magnetic member 35 and the surface of the ball 21. The fifth fixed magnetic member 35 has a pole opposite (e.g., south pole) to that of the first to fourth fixed magnetic members 31 to 34 directed toward the center of the ball 21, and is magnetized 25 to have a magnetic charge about twice the magnetic charge that

of the first to fourth fixed magnetic members 31 to 34. The fifth fixed magnetic member 35 is magnetically coupled to one end of any of the three bar members 26 to 28 embedded in the ball 21.

5 The fifth fixed magnetic member 35 has a cuboid shape. The fifth fixed magnetic member 35 is made of, for example, a rare-earth magnet which, though small in size, generates a powerful magnetic coupling and is easy to process.

[0036] The first to fourth fixed magnetic members 31 to 34 and the fifth fixed magnetic member 35 are fixed to the iron case 22.

10 FIG. 6 is a diagram showing magnetic fluxes generated by the first to fifth fixed magnetic members 31 to 35 and the case 22. If the configuration is such as that of the trackball 2 according to

Embodiment 1 first embodiment, a magnetic circuit such as magnetic fluxes 36A and 36B is established, as shown in FIG. 6. This further

15 increases the magnetic attraction between the ends of the moving-magnet member and the first to fifth fixed magnetic members 31 to 35, and also inhibits the magnetic force from acting outside the case 22. Accordingly, it is possible to prevent magnetic dust, such as iron powder, from being adhered to the case 22 and to prevent

20 devices, such as a watch worn by the user, from getting damaged.

[0037] Next, in the trackball 2 having a configuration such as the one described above, the position of the ball 21 in a normal state, i.e., in a state in which the user is not performing any operation, is described. Of the three bar members 26 to 28 embedded

25 in the ball 21, both ends of two bar members present on the XY

plane are strongly attracted to the first and third fixed magnetic members 31 and 33 and the second and ~~third~~fourth fixed magnetic members 32 and 34. One end of a bar member other than the above two bar members present on the Z axis is strongly attracted to 5 the fifth fixed magnetic member 35. Thus, the ball 21 rests stably in a state in which the ball 21 is in the closest contact with the first to fifth fixed magnetic members 31 to 35.

[0038] Next, movement of the trackball 2 when rolling the ball 21 is described. First, it is assumed that the ball 21 is at rest 10 in a position shown in FIGS. 3 and 4. That is, both ends 26A and 26B of the bar member 26 are respectively attracted to the first and third fixed magnetic members 31 and 33 by magnetic coupling. Both ends 27A and 27B of the bar member 27 are respectively attracted to the second and fourth fixed magnetic members 32 and 34 by magnetic 15 coupling. One end 28B of the bar member 28 is attracted to the fifth fixed magnetic member 35 by magnetic coupling. Thus, the bar member 26 lies on the Y axis, the bar member 27 lies on the X axis, and the bar member 28 lies on the Z axis.

[0039] In such a state, if the user rotates the ball 21 in the 20 forward direction of the Y axis (in the direction of the arrow Y, shown in FIGS. 2 and 3) by touching ~~with the hand or finger~~ the upper portion of the ball 21 exposed from the round hole of the cover plate 24 with his hand or finger, a torque is applied 25 to the ball 21 in the direction of the arrow Y. Accordingly, the ball 21 is rotated while causing the roller 40 (serving as a support

portion) and the roller 42 to also rotate but sliding on the roller 41. The rotation axis of the ball 21 in this state is the central axis of the bar member 27, i.e., the axis that connects between the second fixed magnetic member 32 and the fourth fixed magnetic member 34. In this case, the ball 21 rotates against the attraction of the first and third fixed magnetic members 31 and 33 to both ends 26A and 26B of the bar member 26 and the attraction of the fifth fixed magnetic member 35 to one end 28B of the bar member 28.

10 [0040] FIG. 7 is a diagram showing a state in which the ball 21 is in the process of rotating. When the rotation angle of the ball 21 is greater than about 45° , which is the mid-angle between the bar members 26 and 28, the force with which both ends 28A and 28B of the bar member 28 are attracted to the first and third fixed 15 magnetic members 31 and 33 increases. In addition, the force with which the one end 26A of the bar member 26 is attracted to the fifth fixed magnetic member 35 increases. Accordingly, the ball 21 naturally rotates to a position of about 90° with respect to this rotation direction, and thus is poised at a stable position.

20 If the user continues to apply torque to the upper portion of the ball 21, the ball 21 rotates in the same manner so as to be poised at a stable position every 90° . At this point, the user who manipulates the trackball 2 continuously perceives a resistance such that the rotation feels heavy or light every 90° rotation 25 due to the attraction of the first and third fixed magnetic members

31 and 33 to the bar members 26 and 28, i.e., magnetic coupling, whereby the user experiences a crisp click with the hand or finger.

[0041] Also, in cases where the ball 21 is rotated in the direction opposite to the direction described above (the reversed 5 direction of the Y axis) or where the ball 21 is rotated in either the forward or reversed direction of the X axis, the user experiences a crisp click every 90° rotation.

[0042] Even if the user applies a force to the ball 21 at an angle slightly deviated from the X or Y axis direction, the ball 10 21 rotates the forward or reversed direction of either the X or Y axis direction. This is due to a rotation direction limiting effect provided by the first to fourth fixed magnetic members 31 to 34. That is, in the case of rotating the ball 21 in the forward or reversed direction of either the X or Y axis, the ball 21 is 15 rotated against the attraction of any two opposing fixed magnetic members among the first to fourth fixed magnetic members 31 to 34. On the other hand, in the case of rotating the ball 21 in directions other than the above-described directions, the ball 21 is rotated against all the attractions of the fixed magnetic 20 members. Therefore, it is difficult to rotate the ball 21 in directions other than the forward and reversed directions of the X and Y axis directions. Accordingly, even if a force is applied to the ball 21 at a slightly deviated angle, the ball 21 rotates in the X or Y axis direction in which the ball is easily rotated.

25 [0043] Next, the effect of the fifth fixed magnetic member 35

is described. In order to rotate the ball 21, the user needs to rotate the ball 21 in the X or Y axis direction against the attractions exerted by the fixed magnetic members. For example, in the case of rotating the ball 21 in the forward direction of 5 the Y axis, the contact force between the ball 21 and the roller 40 decreases, whereby the ball 21 is apt to approach the first fixed magnetic member 31.

[0044] On the assumption that the fifth fixed magnetic member 35 is absent, if the user applies a force to the ball 21 in the 10 forward direction of the Y axis against the attraction of the first and third fixed magnetic members 31 and 33, the ball 21 is pulled away from the roller 40, and thus the distance between the ball 21 and the first fixed magnetic member 31 is reduced. Accordingly, while the attraction between the first fixed magnetic member 31 15 and the end 26A of the bar member 26 rapidly increases, the attraction between the third fixed magnetic member 33 and the end 26B of the bar member 26 rapidly decreases. Hence, the magnetic force applied to the ball 21 becomes unstable, whereby the rotation of the ball 21 becomes unstable.

20 [0045] On the other hand, when the fifth fixed magnetic member 35 is present as with the present embodiment, the contact force between the ball 21 and each of the rollers 40 to 42 increases by the attraction of the fifth fixed magnetic member 35. Therefore, even if the ball 21 is rotated in either the X or Y axis direction, 25 it is possible to prevent the ball 21 from being pulled away from

each roller, and consequently, the ball 21 approaches any of the first to fourth fixed magnetic members 31 to 34, thereby preventing the magnetic force applied to the ball 21 from becoming unstable. Hence, the rotation of the ball 21 becomes stable, and the user experiences the same crisp click regardless of whether the ball 21 is rotated in the X or Y axis direction, ~~the user experiences the same crisp click~~. The present inventors have experimentally found that in order to stably rotate the ball 21, the magnetic force of the fifth fixed magnetic member 35 should be twice that the magnetic force of each of the first to fourth fixed magnetic members 31 to 34.

[0046] FIGS. 8 to 10 are illustrative drawings showing application examples of the in-vehicle device controller 1 having the trackball 2 mounted thereon. With reference to FIGS. 8 to 15 10, application examples of the in-vehicle device controller 1 are described by using air-conditioning system settings as an example. In the present embodiment, it is assumed that an air-conditioning system, an audio system, a TV, a navigation system, and information are assigned, as control objects, to the buttons 20 4 to 8, respectively, but the control objects and order to be assigned to the buttons 4 to 8 are not limited to those described above.

[0047] In the case of air-conditioning system setting, the user presses the button 4 shown in FIG. 2 to select the air-conditioning system as a control object. When the button 4 is pressed, the 25 in-vehicle device controller 1 allows the display 3 to display

an exemplary display 100, such as those shown in FIGS. 8 to 10. In the setting of the air-conditioning system, the in-vehicle device controller 1 can adjust three settings, i.e., air outlet, temperature, and airflow volume, according to the user's operation.

- 5 The user can see which setting item the user can change, by the position of a setting item selection frame 110.

[0048] The exemplary display 100 in FIG. 8 shows a state in which the setting of an air outlet can be made. The exemplary display 100 in FIG. 9 shows a state in which the setting of 10 temperature can be made. The exemplary display 100 in FIG. 10 shows a state in which the setting of airflow volume can be made.

[0049] When the button 4 is pressed, the in-vehicle device controller 1 allows the display 3 to display the setting item selection frame 110 at the position where the previous setting 15 was made. The position of the setting item selection frame 110 can be changed by rotating the ball 21 by applying a force to the ball 21 in the forward or reversed direction of the X axis. To change from the setting of an air outlet shown in FIG. 8 to the setting of airflow volume shown in FIG. 10, the user rotates the 20 ball 21 180° in the forward direction of the X axis. At this point, the user experiences a crisp click twice with, for example, the hand or finger. As described above, to select another setting item which is different from that currently selected by the setting item selection frame 110, the user rotates the ball 21 by applying 25 a force in the direction in which the desired item is displayed.

Thereby, the setting item can be changed. This operation method is sensory and natural for the user. Since the user feels a resistance every 90° rotation, it is possible to prevent the user from over-rotating the ball 21 and from rotating the ball 21 in 5 the wrong direction. Thus, the user can securely change the position of the setting item selection frame 110 to two items away from the current position on the right, for example.

[0050] Next, the change of the settings for the three setting items is described. First, the setting of an air outlet is 10 described, with reference to FIG. 8. Symbols 101 to 105 indicate the locations of the air outlet of the air-conditioning system in a vehicle. The user can change the location of the air outlet by selecting the symbols.

[0051] When the symbol 101 is selected, the in-vehicle device controller 1 controls the air-conditioning system to blow the air 15 from the lower part of the windscreen (windshield) to prevent the fogging of the windscreen. When the symbol 102 is selected, the in-vehicle device controller 1 controls the air-conditioning system to blow the air from the lower part of the windscreen to 20 prevent the fogging of the windscreen, and a vent near the feet. When the symbol 103 is selected, the in-vehicle device controller 1 controls the air-conditioning system to blow the air from the upper portion of the instrument panel. When the symbol 104 is selected, the in-vehicle device controller 1 controls the 25 air-conditioning system to blow the air from the upper portion

of the instrument panel and a vent near the feet. When the symbol 105 is selected, the in-vehicle device controller 1 controls the air-conditioning system to blow the air from a vent near the feet. When the symbol 106 is selected, the in-vehicle device controller 5 1 controls the air-conditioning system to an automatic setting for blowing air from an appropriate air outlet(s).

[0052] An air outlet selection frame 107 encloses the symbol
| that is currently selected by the user. In the example shown in
| FIG. 8, the symbol 104 is selected. The air outlet setting can
10 be changed only when the setting item selection frame 110 is at
the position enclosing the symbols 101 to 106. FIG. 8 shows a
| state in which the setting of an air outlet can be changed. To
change the air outlet, the user rotates the ball 21 in the forward
or reversed direction of the Y axis. Each time the user rotates
15 the ball 21 by 90° by applying a force in the forward direction
of the Y axis (the forward direction of the vehicle), the user
experiences a crisp click, and can select the air outlet in the
order of the symbols 103, 102, and 101. In contrast, each time
the user rotates the ball 21 by 90° by applying a force in the
20 reversed direction of the Y axis (the backward direction of the
vehicle), the user experiences a crisp click, and can select the
air outlet in the order of the symbols 105 and 106. There are
six options available for the air outlet selection. The user
experiences a crisp click each time the user changes the symbol.
25 [0053] If the ball 21 is rotated in the forward direction of

the Y axis in a state in which the symbol 101 is selected, the in-vehicle device controller 1 allows the selection of the symbol 106. On the other hand, if the ball 21 is rotated in the reversed direction of the Y axis in a state in which the symbol 106 is selected,
5 the in-vehicle device controller 1 allows the selection of the symbol 101. As described above, the in-vehicle device controller 1 provides a user interface that allows the user to make a selection or change with a minimum operation.

[0054] The in-vehicle device controller 1 controls the air-conditioning system such that even if the user makes other settings or performs a functional control on other than the air-conditioning system, the selected air outlet is maintained until another setting is made to the air outlet.

[0055] Next, the setting of temperature is described, with reference to FIG. 9. The in-vehicle device controller 1 allows a set temperature display part 113 to display an in-vehicle temperature which is currently set, and allows a set temperature display bar 112 to display the currently set temperature against the temperature graduation. The set temperature can be changed
20 only when the setting item selection frame 110 is at the position enclosing the set temperature display part 113, the set temperature display bar 112, and the temperature graduation. In a state in which the set temperature can be changed, the in-vehicle device controller 1 can change the set temperature of the air-conditioning
25 system by rotating the ball 21 in the forward or reversed direction

of the Y axis.

[0056] If the user rotates the ball 21 by applying a force to the ball 21 in the forward direction of the Y axis (the forward direction of the vehicle), the in-vehicle device controller 1 raises the set temperature. By contrast, if the user rotates the ball 21 by applying a force to the ball 21 in the reversed direction of the Y axis (the backward direction of the vehicle), the in-vehicle device controller 1 lowers the set temperature. The in-vehicle device controller 1 changes the set temperature display part 113 and the set temperature display bar 112 in accordance with the change of the set temperature.

[0057] The air-conditioning system of the present embodiment can change the set temperature in increments of 0.5°C. Therefore, the in-vehicle device controller 1 allows the 90° rotation of the ball 21 to correspond to the temperature of 0.5°C, and thus changes the set temperature of the air-conditioning system. Thereby, the user experiences a crisp click every 0.5°C increment of change.

[0058] The temperature setting range in the air-conditioning system of the present embodiment is between 16°C and 32°C. Thus, when the set temperature is 16°C, even if the user performs an operation of lowering to lower the temperature, the in-vehicle device controller 1 cannot change the set temperature. Similarly, when the set temperature is 32°C, even if the user performs an operation of raising to raise the temperature, the in-vehicle device controller 1 cannot change the set temperature.

[0059] The in-vehicle device controller 1 does not change the temperature once it is set, even if the user makes other settings or performs a functional control on other than the air-conditioning system, until the user changes the set temperature.

5 [0060] Next, the setting of airflow volume is described, with reference to FIG. 10. The setting of airflow volume provides three modes. The first mode is a manual setting for manually setting the airflow volume freely. When the manual setting mode is selected, the in-vehicle device controller 1 increases the brightness of 10 a manual airflow volume setting frame 123 on the display 3. The second mode is an automatic airflow volume setting in the air-conditioning system. When the automatic airflow volume setting mode is selected, the in-vehicle device controller 1 increases the brightness of an automatic airflow volume setting 15 frame 124 on the display 3. The third mode is a no-airflow setting. When the no-airflow setting mode is selected, the in-vehicle device controller 1 increases the brightness of a no-airflow frame 125 on the display 3.

[0061] In the example shown in FIG. 10, the brightness of the 20 manual airflow volume setting frame 123 is increased, indicating that the manual setting mode is selected. An airflow volume display bar 122 indicates the airflow volume set by the manual setting mode. The lower end of a set range 121 indicates that there is no airflow. The upper end of the set range 121 indicates the maximum 25 airflow. The airflow volume can be changed only when the setting

item selection frame 110 is at the position enclosing the manual airflow volume setting frame 123, the automatic airflow volume setting frame 124, and the no-airflow frame 125. In a state in which the airflow volume can be changed, when the ball 21 is rotated
5 in the forward or reversed direction of the Y axis, the in-vehicle device controller 1 controls the air-conditioning system to change the airflow volume.

[0062] In the example shown in FIG. 10, the brightness of the manual airflow volume setting frame 123 is increased, indicating
10 that the manual setting mode is selected. In this case, if the user rotates the ball 21 by applying a force to the ball 21 in the forward direction of the Y axis (the forward direction of the vehicle), the in-vehicle device controller 1 controls the air-conditioning system to increase the airflow volume. By
15 contrast, if the user rotates the ball 21 by applying a force to the ball 21 in the reversed direction of the Y axis (the backward direction of the vehicle), the in-vehicle device controller 1 controls the air conditioning system to reduce the airflow volume.
For the manual setting mode, the airflow volume can be adjusted
20 in five levels from no airflow to the maximum airflow. Hence, in the manual setting mode where the brightness of the manual airflow volume setting frame 123 is increased, each time the user rotates the ball 21 by 90°, the in-vehicle device controller 1 changes the airflow volume by one level, along with an appropriate update
25 of the airflow volume display bar 122.

[0063] In a state in which the airflow volume is at the maximum volume in the manual control, even if the user performs an operation of increasing to increase the airflow volume, the in-vehicle device controller 1 does not change the airflow volume. On the other hand, in a state in which there is no airflow in the manual control, if the user performs an operation of reducing to reduce the airflow volume, i.e., the user rotates the ball 21 by 90° in the reversed direction of the Y axis, the in-vehicle device controller 1 switches from the manual setting mode to the automatic airflow volume setting mode, and increases the brightness of the automatic airflow volume setting frame 124. If the user further rotates the ball 21 by 90° in the reversed direction of the Y axis, the in-vehicle device controller 1 switches from the automatic airflow volume setting mode to the no-airflow setting mode and increases the brightness of the no-airflow frame 125. Further, even if the ball 21 is rotated in the reversed direction of the Y axis in the no-airflow setting mode, the in-vehicle device controller 1 does not change the airflow volume.

[0064] On the other hand, in the no-airflow setting mode, if the user rotates the ball 21 by 90° by applying a force to the ball 21 in the forward direction of the Y axis (the forward direction of the vehicle), the in-vehicle device controller 1 switches from the no-airflow setting mode to the automatic airflow volume setting mode and increases the brightness of the automatic airflow volume setting frame 124. If the user further rotates the ball 21 by

90° by applying a force to the ball 21 in the forward direction of the Y axis (the forward direction of the vehicle), the in-vehicle device controller 1 switches from the automatic airflow volume setting mode to the manual setting mode and increases the brightness

5 of the manual airflow volume setting frame 123.

[0065] As described above, in ~~Embodiment 1~~ the first embodiment, a fixed magnetic member is provided beneath the ball so that the force to attract the ball acts at all times, whereby a stable operational feel can be provided to the user. In addition, since

10 the in-vehicle device controller allows the screen provided on the display and the movement of the trackball to correspond to each other, an interface for intuitively controlling in-vehicle devices can be provided.

[0066] In the above embodiment, the ball has three bar members embedded therein on three axes. Alternatively, in order to provide a crisp click to the rotation only in one direction (for example, the Y direction), the ball would only need to have two unmagnetized bar members embedded therein on at least two axes orthogonal to each other. In this case, a crisp click is provided by magnetic

20 coupling between the magnets fixed to side surfaces of the case and the magnetic members embedded in the ball. In addition, because the magnet fixed to the bottom surface of the case attracts the magnetic members embedded in the ball, a stable operational feel can be provided to the user.

25 [0067] Moreover, in the above embodiment, the ball has bar

members embedded therein, but the structure is not limited thereto as long as the ball is formed in a manner such that eight surfaces of the ball orthogonal to the X, Y, and Z axes are made of magnetic members. For example, the eight surfaces may have embedded therein 5 cylindrical or polygonal columns, wedge-shaped magnetic members, or spherical members. In addition, other shapes may be employed. That is, the ball should have embedded therein at least one magnetic member so as to be magnetically coupleable in directions of first, second, and third axes intersecting with one another at the center 10 of the ball and orthogonal to one another. The same applies to the case where magnetic members are embedded in the ball on at least two axes. That is, the ball should have embedded therein at least one magnetic member so as to be magnetically coupleable in directions of first and second axes intersecting with one another 15 at the center of the ball and orthogonal to one another.

[0068] In the above embodiment, the bar members are embedded in the ball on the X, Y, and Z axes, but the configuration is not limited thereto. That is, bar members may be embedded at predetermined positions so as not to be orthogonal to each other. 20 In this case, because the ball is stably poised at a predetermined position, the user experiences a crisp click every predetermined angle.

[0069] The above-described first to fifth fixed magnetic members may be permanent magnets or electromagnets, or any type 25 of magnet can be used as long as the member is magnetizable.

[0070] In the process of making a setting, if any of the buttons 4 to 8 for selecting a control object is pressed, the in-vehicle device controller 1 allows the display 3 to display a control screen for the selected object, allowing the user to control the selected
5 object.

[0071] In the above embodiment, the trackball of the present invention is applied to a vehicle, but the application is not limited thereto. For example, the trackball of the present invention can be applied to various electronic devices, such as air-conditioners, 10 audio systems, TV remote controllers, telephones, and mobile phones. The application range is very wide.

[0072] {Second Embodiment-2}

FIG. 11 is a cross-sectional view showing a trackball 2a according to Embodiment 2a second embodiment of the present invention. FIG. 11 is equivalent to FIG. 3 in Embodiment 1the first embodiment. In FIG. 11, the components similar to those found in Embodiment 1the first embodiment are designated by like reference numerals and the descriptions thereof are omitted. In addition, the relationship between an in-vehicle device controller 20 1 and in-vehicle devices 11 is the same as that described in Embodiment 1the first embodiment and thus FIG. 2 is incorporated in the present embodiment.

[0073] The trackball 2a includes a ball 21, a case 22, first to fourth fixed electromagnets 331, 332, 333, and 334, a fifth 25 fixed electromagnet 335, a sixth fixed electromagnet 338336, an

electromagnet controller 340, rollers 40, 41, and 42, shafts 43, 44, and 45, shaft bearings 46A, 46B, 47A, 47B, 48A, and 48B, and rotary encoders 50 and 51. The rollers 41 and 42, the shafts 43 to 45, the shaft bearings 46A to 48B, and the rotary encoders 50

5 and 51 are the same as those in Embodiment 1the first embodiment and thus are omitted in the figureFIG. 11.

[0074] In Embodiment 2the second embodiment, the first to fourth fixed magnetic members 31 to 34 in Embodiment 1the first embodiment are replaced with the first to fourth fixed electromagnets 331 to 334, and the fifth fixed magnetic member 35 in Embodiment 1the first embodiment is replaced with the fifth fixed electromagnet 335. In addition, the sixth fixed electromagnet 336 is additionally provided in the second embodiment. FIG. 12 shows a state in which the ball 21 is rotated 45° from the position shown in FIG. 11 with the central axis of a bar member 27, i.e., the axis connecting between fixed the magnetic members 332 and 334, as the rotation axis. The sixth fixed electromagnet 336 is arranged so as to be, when the ball 21 is rotated in a state as shown in FIG. 12, at a position which is on the extension of either a bar member 26 or 28.

[0075] The electromagnet controller 340 changes the state of either the presence or absence of the magnetic force of the first to sixth fixed electromagnets 331 to 336, and the magnetic force strength of the first to sixth fixed electromagnets 331 to 336, 25 according to a mode signal concerning a menu which is sent from

the in-vehicle device 11 via the in-vehicle device controller 1.

[0076] If the electromagnet controller 340 controls the electromagnets such that the first to fourth and the sixth fixed electromagnets 331 to 334 and 336 all have the same magnetic force 5 and the fifth fixed electromagnet 335 has a magnetic force twice
| that the magnetic force of the first to fourth and the sixth fixed
| electromagnets 331 to 334 and 336 and has a polarity opposite to
| that the polarity of the first to fourth and the sixth fixed
| electromagnets 331 to 334 and 336, the ball 21 can stably be poised
10 even in a state shown in FIG. 12. Thus, the user experiences a crisp click every 45° at the time of rotating the ball 21. When a crisp click of 45° is required, the in-vehicle device 11 sends to the in-vehicle device controller 1 a mode signal to obtain such magnetic forces.

15 [0077] If the electromagnet controller 340 controls the electromagnets such that the first to fourth fixed electromagnets 331 to 334 all have the same magnetic force and the fifth fixed electromagnet 335 has a magnetic force twice that the magnetic
| force of the first to fourth fixed electromagnets 331 to 334 and
20 has a polarity opposite to that the polarity of the first to fourth fixed electromagnets 331 to 334, the ball 21 can stably be poised, as with Embodiment 1 in the first embodiment, in a state shown in FIG. 11, and thus the user experiences a crisp click every 90° at the time of rotating the ball 21. When a crisp click is required 25 every 90°, the in-vehicle device 11 sends to the in-vehicle device

controller 1 a mode signal to obtain such magnetic forces.

[0078] Next, with reference to FIGS. 8 to 10, an application

example of the in-vehicle device controller 1 according to

~~Embodiment 2~~ the second embodiment is described by using an

5 air-conditioning system setting as an example. As in ~~Embodiment~~

~~1~~ the first embodiment, when the button 4 shown in FIG. 2 is pressed,

the in-vehicle device controller 1 allows the display 3 to display

an exemplary display 100, such as those shown in FIGS. 8 to 10.

[0079] In the case of controlling the air-conditioning system,

10 the in-vehicle device controller 1 determines, according to a mode

signal sent from the air-conditioning system, whether or not to

generate the magnetic force of the sixth fixed electromagnet 336,

and controls the electromagnet controller 340.

[0080] For the air-conditioning system, the user can make

15 settings of an air outlet, temperature, and airflow volume. The

user can see which setting item the user can change, by the position

of the setting item selection frame 110. The position of the

setting item selection frame 110 can be changed by rotating the

ball 21 by applying a force to the ball 21 in the forward or reversed

20 direction of the X axis, as in ~~Embodiment 1~~ the first embodiment.

[0081] First, the setting of the air outlet is described. When

the setting of air outlet is selected, the in-vehicle device

controller 1 controls the electromagnet controller 340 in a manner

such that only the first to fifth fixed electromagnets 331 to 335

25 generate a magnetic force and the sixth fixed electromagnet 336

does not generate a magnetic force. Thus, the user can make the setting of air outlet in the same manner as that of ~~Embodiment~~
~~the first embodiment.~~

[0082] Next, the setting of temperature is described, with
5 reference to FIG. 9. When the temperature setting is selected,
the in-vehicle device controller 1 controls the electromagnet
controller 340 in a manner such that all of the first to sixth
fixed electromagnets 331 to 336 generate a magnetic force. The
in-vehicle device controller 1 controls the air-conditioning
10 system such that each time the ball 21 is rotated 45° in the forward
or reversed direction of the Y axis the temperature changes in
increments of 0.5°C. The operation is the same as that of
~~Embodiment~~
~~the first embodiment,~~ except that the user experiences
a crisp click every 45° rotation.

15 [0083] The temperature setting is not one where one option is
selected from just a few options, like the air outlet setting,
but is one where a value for the temperature is adjusted gradually
in small increments—gradually. Thus, the number of levels for
the selection is greater than that for the air outlet setting,
20 and therefore it is preferable that the rotation angle of the ball
21 required for one level adjustment be small. Hence, it is
advantageous that the in-vehicle device controller 1 controls the
temperature setting such that the set temperature changes in
increments of 0.5°C every 45° of rotation.

25 [0084] Next, the setting of airflow volume is described, with

reference to FIG. 10. In the airflow volume setting mode, when the manual airflow volume setting mode is selected, the in-vehicle device controller 1 controls the electromagnet controller 340 in a manner such that all of the first to sixth fixed electromagnets 5 331 to 336 generate a magnetic force. When the automatic airflow volume setting mode is selected, the in-vehicle device controller 1 controls the electromagnet controller 340 in a manner such that only the first to fifth fixed electromagnets 331 to 335 generate a magnetic force. When the no-airflow setting mode is selected, 10 the in-vehicle device controller 1 controls the electromagnet controller 340 in a manner such that only the first to fifth fixed electromagnets 331 to 335 generate a magnetic force.

[0085] When the manual airflow volume setting mode is selected, because the magnetic force is generated by all of the first to 15 sixth fixed electromagnets 331 to 336, the in-vehicle device controller 1 controls the air-conditioning system in a manner such that the airflow volume changes by one level each time the ball 21 is rotated 45°. In the manual airflow volume setting mode, when the airflow volume is at minimum volume, if the ball 21 is 20 rotated 45°, the in-vehicle device controller 1 controls the air-conditioning system to be the automatic airflow volume setting mode and also controls the electromagnet controller 340 so that the sixth fixed electromagnet 336 does not generate a magnetic force. On the other hand, in the automatic airflow volume setting 25 mode, if the ball 21 is rotated 90° in the forward direction of

the Y axis, the in-vehicle device controller 1 controls the air-conditioning system to be the manual airflow volume setting mode and also controls the electromagnet controller 340 so that the sixth fixed electromagnet 336 generates a magnetic force.

5 Except for these, the control is the same as that of ~~Embodiment~~
the first embodiment.

[0086] As described above, in ~~Embodiment 2~~the second embodiment, by controlling the magnetic force of the fixed electromagnets, the frequency of the crisp click can be adjusted, depending on
10 which parameter of a given in-vehicle device is to be controlled.

[0087] In the above second embodiment, fixed electromagnets are used, but if the purpose is only to provide a crisp click every
| 45° rotation, the trackball may be configured by using only fixed
magnetic members.

15 [0088] In addition, the configuration may be such that only the sixth fixed electromagnet is an electromagnet and the first to fifth fixed electromagnets are replaced with permanent magnets.

[0089] In the case of using fixed magnetic members, the presence or absence of the magnetic force of the fixed magnetic members
20 may be switched by a motor or solenoid by providing a mechanical system, such as a boulder mount used in optical experiments, in which the magnetic force does not act on the moving-magnet member
25 of the ball 21. Thus, even if fixed magnetic members are used, it is possible to switch between a crisp click every 90° rotation
25 and a crisp click every 45° rotation.

[0090] By controlling fixed electromagnets so as not to generate a magnetic force, a trackball that does not provide a crisp click can also be provided. Thus, by the combination of fixed electromagnets generating a magnetic force and fixed electromagnets not generating a magnetic force, a wide variety of applications can be offered; for example, an ability to scroll on the map in a navigation system without a crisp click could also be provided.

[0091] In order to provide a crisp click each time the ball is rotated 45°, instead of providing the sixth fixed electromagnet, a moving-magnet member embedded in the ball may be configured in the manner described in FIG. 13. FIG. 13 is a cross-sectional view of the ball 21 taken along the YZ plane. Bar members 301 and 302 are orthogonal to a bar member 27 and constitute an angle of 45° with respect to each of bar members 26 and 28, and are arranged such that the central axes thereof penetrate through the center of the ball. Thereby, even without the sixth fixed electromagnet, when the bar member 27 is the central axis, a crisp click every 45° rotation can be provided to the user.

[0092] In addition, as shown in FIG. 14, bar members 303, 304, 305, and 306 may be orthogonal to a bar member 27 and may make an angle of 30° or 60° with respect to either of bar members 26 and 28, and may be arranged such that the central axes thereof penetrate through the center of the ball. Thereby, when the bar member 27 is the central axis, a crisp click every 30° rotation

can be provided to the user.

[0093] Needless to say, by embedding a larger number of bar members (preferably, an even number of bar members) in the ball, it becomes possible to provide crisp clicks at a finer resolution.

5 [0094] {Third Embodiment-3}

FIG. 15 is a cross-sectional view of a trackball 2b taken along a YZ plane according to the present third embodiment of the present invention. FIG. 15 is a cross-sectional view equivalent to that of FIG. 3 in Embodiment 1the first embodiment.

10 FIG. 16 is a cross-sectional view equivalent to that of FIG. 4 in Embodiment 1the first embodiment. FIG. 17 is a cross-sectional view of a ball 21a taken along a YZ plane. In FIGS. 15 to 17, the components similar to those found in Embodiment 1the first embodiment are designated by like reference numerals and the 15 descriptions thereof are omitted.

[0095] The trackball 2b according to Embodiment 3the third embodiment is configured in the same manner as that of Embodiment 1the first embodiment, except for eliminating the second and forth fixed magnetic members 32 and 34 and one bar member (the bar member 20 27 in FIG. 16) among the three bar members on three axes orthogonal to each other.

[0096] As shown in FIG. 15, the ball 21a according to Embodiment 3the third embodiment has embedded therein four bar members 26, 28, 301a, and 302a on the YZ plane. The four bar members 26, 28, 25 301a, and 302a intersect with one another at the center of the

ball 21a and are embedded in the ball such that the angles between adjacent bar members ~~have the same measure~~are equal to each other.

Both ends of each bar member reach the surface of the ball 21a or the vicinity of the surface of the ball 21a.

5 [0097] First and third fixed magnetic members 31 and 33 are magnetically coupled to ends of a bar member so that the ball 21a rotates around the central axis of the bar member (in FIG. 15, the central axis of the bar member 26) penetrating through the center of the ball 21a. A fifth fixed magnetic member 35 is
10 magnetically coupled to an end of the bar member 28.

[0098] A cover plate 324 for covering the top surface of a case 22 has an opening portion for exposing the upper portion of the ball 21a. The upper portion of the ball 21a exposed from the cover plate 324 restricts a portion that can be touched with a hand or
15 finger. Specifically, the ball 21a is exposed from the cover plate 324 so that the ball 21a rotates about a quarter of the diameter of the ball 21a, i.e., 45° which is the angle between the plurality of bar members. The attraction of the fifth fixed magnetic member 35 has a strength such that the attraction acts on the range of
20 45° in all directions around any bar member situated so as to extend along the Z axis direction.

[0099] When the user rotates the ball 21a by applying a force to the ball 21a in the X axis direction, the ball 21a moves around the bar member 26. However, by the attraction of the fifth fixed
25 magnetic member 35, the force to return to the original states

acts on the ball 21a. Thus, when the user releases the hand or finger from the ball 21a, the ball 21a rotates in the direction opposite to the direction in which the operation in the X axis direction is performed due to the attraction of the fifth fixed

5 magnetic member 35, and is stabilized at the time when the bar member 28 lies on the fifth fixed magnetic member 35. Thus, in
| Embodiment 3the third embodiment, the ball 21a cannot be rotated
in the X axis direction.

[0100] As described above, in Embodiment 3the third embodiment,
10 since the ball 21a cannot rotate in the X axis direction and returns to the original position, the feeling of manipulating a joy stick can be provided to the user. In addition, because the bar members 26, 28, 301a, and 302b are arranged with a 45° angle between the bar members, when the ball is rotated in the Y axis direction,
15 the user experiences a crisp click every 45° rotation. Thus, the operational feel can be made to be different between the X axis direction and the Y axis direction, and therefore it is advantageous to prevent, for example, misoperation.

[0101] When using a trackball according to Embodiment 3the third embodiment, an in-vehicle device controller may control an in-vehicle device such that when the ball is rotated greater than a predetermined angle (e.g., 30°) in the X direction, this operation is regarded as an operation in the X direction. In this case, in the operation in the X axis direction, the ball returns to the
25 original position each time an operation is performed, such as

a joy stick, and therefore it is advantageous in the case of making a selection for a menu with a few options. On the other hand, in the operation in the Y axis direction, a rotation operation with a crisp click can be performed, and thus it is advantageous
5 in the case of making a selection for a menu with many options or setting a value.

[0102] It is also possible to arrange a plurality of bar members 26, 28, 303, 304, 305, and 306 such that the angles between the bar members have the same measure, as shown in FIG. 18. This
10 provides the user a crisp click each time the ball rotates 30°.

~~These~~ The number of bar members are ~~is~~ preferably in an even number.

[0103] It is not necessary that for the cover plate 324 covering the top surface of the case 2 to have a round hole made in a flat plate. That is, the rotatable angle by one operation with a hand
15 may be made different between the X and Y directions. It is preferable that the Y-direction rotatable angle be set to a value greater than that of the X-direction rotatable angle, by, for example, making a large oval hole in the cover plate 324 in the Y direction.

20 [0104] The first, third, and fifth fixed magnetic members 31, 33, and 35 may be a unit that is capable of switching between the presence and absence of the magnetic force of, for example, electromagnets. In this case, by eliminating the magnetic force of electromagnets, a trackball in which the ball 21a freely rotates
25 can be provided.

[0105] {Fourth Embodiment-4}

FIG. 19 is an external perspective diagram showing a cockpit of a vehicle equipped with a trackball 401 according to ~~Embodiment 4~~ a fourth embodiment of the present invention. In FIG. 5 19, a steering wheel 400 is provided with the trackball 401 and a button 402. The trackball 401 and the button 402 comprise an in-vehicle device controller according to ~~Embodiment 4~~ the fourth embodiment.

[0106] The trackball 401 is a device used for controlling 10 in-vehicle devices which are control objects, and is mounted on a spoke portion of the steering wheel. The trackball 401 is provided at a location where an operation is easily performed by the thumb. In FIG. 19, the trackball 401 is provided at a location where an operation is easily performed by the thumb of the right 15 hand, but the location of the trackball 401 is not limited thereto.

[0107] The button 402 is provided to select any number of 20 in-vehicle devices to be controlled, and is mounted on a spoke portion of the steering wheel. The button 402 is provided at a location where an operation is easily performed by the thumb. In FIG. 19, the button 402 is provided at a location where an operation is easily performed by the thumb of the left hand, but the location of the button 402 is not limited thereto.

[0108] As in ~~Embodiment 1~~ the first embodiment, a display 3 displays a menu screen for controlling an in-vehicle device, 25 according to instructions from the in-vehicle device controller.

[0109] The structure of the trackball 401 is the same as that described in ~~Embodiment 1~~the first embodiment. Therefore, FIGS. 3 to 5 are incorporated in the present embodiment. It is to be noted, however, that in ~~Embodiment 4~~the fourth embodiment the 5 trackball 401 is arranged such that the XY plane is a plane made by the steering wheel 400. In FIG. 19, X, Y, and Z axes are shown for clarity. As in FIG. 1, the center of the X, Y, and Z axes lies at the center of a ball included in the trackball 401.

[0110] When the driver is not touching the ball 21, a fifth 10 fixed magnetic member 35 attracts the ball 21. Thus, as shown in FIG. 3, the ball 21 is at rest with close contact with a roller 40.

[0111] Next, the operation method of the trackball 401 is 15 described. The driver operates the ball 21 by the thumb or any other finger in either the X or Y direction with the steering wheel being held by the driver. To rotate the ball 21, the frictional force between the finger and the ball 21 needs to overcome the magnetic force that tries to rest the ball 21. Therefore, in order 20 to rotate the ball 21, the driver needs to press the ball 21 with a finger while rotating. Accordingly, during an operation, the ball 21 cannot be pulled away from the rollers 40, 41, and 42.

[0112] The method of controlling in-vehicle devices using an 25 in-vehicle device controller is now described. The driver first presses the button 402 provided in the steering wheel to select an in-vehicle device to be controlled. At this point, the

in-vehicle device controller allows the display 3 to display the device to be controlled, according to the number of times the button 402 is pressed. In addition, the in-vehicle device controller switches a display of the display 3 and shows the current control object with voice (speech). By showing with voice, the driver can acknowledge the currently controlled in-vehicle device without viewing the display 3.

[0113] The driver manipulates the trackball 401 when the desired in-vehicle device is selected as a control object. Accordingly, the in-vehicle device controller controls movement of the in-vehicle device. For example, in the case of controlling an air-conditioning system, the in-vehicle device controller selects the air outlet or adjusts the temperature or the airflow volume when the trackball 21 is moved in the Y direction. If the trackball 21 is moved in the X direction, the in-vehicle device controller selects the setting of air outlet, temperature, or airflow volume.

These are the same as those described in ~~Embodiment 1~~the first embodiment.

[0114] In the case of controlling an audio system, if the trackball 21 is moved in the forward direction of the Y axis, the in-vehicle device controller turns up the volume, and if the trackball 21 is moved in the reversed direction of the Y axis, the in-vehicle device controller turns down the volume. If the trackball 21 is moved in the X direction, the in-vehicle device controller allows the audio system to select a song to be played,

according to the rotation angle of the trackball.

[0115] As described above, in ~~Embodiment 4~~the fourth embodiment, by providing a trackball in the steering wheel, the driver can easily control in-vehicle devices. In addition, because a trackball used in ~~Embodiment 4~~the fourth embodiment is the same as that used in ~~Embodiment 1~~the first embodiment, an operational feel is good compared to conventional ~~one~~trackballs.

[0116] The shaft bearings 46A, 46B, 47A, 47B, 48A, and 48B may include springs therein ~~springs~~. With this configuration, when the ball 21 is pressed, the shafts 43, 44, and 45 respectively fixed to the rollers 40, 41, and 42 accordingly press the springs of the shaft bearings 46A, 46B, 47A, 47B, 48A, and 48B, and therefore the rollers 40, 41, and 42 can be in contact with the ball 21 at all times. Here, the force of the springs needs to be sufficiently weaker than the force ~~that applied to~~ applied to the ball 21 when the ball 21 is pressed due to magnetic force by the rollers 40, 42, and 42.

[0117] A trackball used in ~~Embodiment 4~~the fourth embodiment may be a trackball according to ~~Embodiment 2~~the second embodiment or may be a trackball according to ~~Embodiment 3~~the third embodiment.

[0118] As described above, in the present invention, a first magnet portion stabilizes a ball portion at predetermined rotation angles. In addition, a second magnet portion attracts the ball portion in the direction of the bottom surface of a case portion at all times. Therefore, even if applying a force to rotate the

ball portion, because there is a force attracting the ball portion in the direction of the bottom surface of the case portion at all times, and because the ball portion is brought in close contact with a support portion for supporting the ball portion, it is

5 possible to prevent the ball portion from coming in contact with the first magnet portion by an operation force, while still providing ~~the user~~ a crisp click to the user. Accordingly, the user can manipulate a trackball with a smooth feel and without rotational play while obtaining a crisp click and stability.

10 [0119] Such a trackball is advantageously used to control electronic devices, such as air-conditioners, navigation systems, and audio systems, even in environments in vehicles where vibration and movement are present.

[0120] By allowing the magnetic force of the second magnet portion to be greater than the magnetic force of the first magnet portion, the force that brings the ball portion in close contact with the support portion is allowed to act surely, making it possible to improve an operational feel.

[0121] By using a third magnet portion, the rotation angle at which a crisp click can be obtained can be set more minutely, and therefore when performing an operation with many options, good operational efficiency can be obtained and misoperation can be prevented. In addition, by switching between the presence and absence of the magnetic force of the third magnet portion, the frequency of a crisp click can be adjusted in accordance with the

number of options, whereby the range of designing a menu increases and operational efficiency is further increased. Moreover, by automatically switching between the presence and absence of the magnetic force of the third magnet portion, depending on which 5 parameter of a given electronic device is to be controlled, operability is further improved.

[0122] For example, the frequency of a crisp click can be changed according to the parameters of control menu screens for controlling electronic devices, and thus an operational feel of the menu becomes 10 more natural and operational efficiency is improved.

[0123] By arranging a plurality of bar members made of an unmagnetized magnetic material on a plane and by limiting the rotation angle of the ball portion, a crisp click can be provided to the user for the rotation in one direction and a feel as if 15 manipulating a joy stick (such that the ball portion tries to return to the original position) can be provided to the user for the rotation in the other direction. For example, the operation based on the ball portion's return to the original position may be assigned with a selection item which allows for a relatively few options, whereas a crisp-clicked operation may be assigned with a selection 20 item which provides a relatively many greater number of options, thereby enabling the user to quickly select a value or option. In addition, this provides the user different operational feels depending on the operation direction, and therefore it is possible 25 to prevent misoperation. Further, this stabilizes the ball

portion, and thus it is possible to prevent misoperation caused by a shake, vibration or movement in the vehicle.

[0124] Trackballs according to the present invention and in-vehicle device controllers using the trackballs can provide 5 a stable operational feel to the user, and are advantageously used as devices for controlling electronic devices.

[0125] While the invention has been described in detail, the foregoing description is in all aspects illustrative and not 10 restrictive. It is to be understood that numerous other modifications and variations can be devised without departing from the scope of the invention.

ABSTRACT OF THE DISCLOSURE

The present invention provides a trackball and an in-vehicle device controller using the trackball. The trackball
5 | provides a stable operational feel and ~~are~~ is easy to operate even in an environment in a vehicle where vibration and movement are present. ~~A~~ The trackball ~~2~~ includes a ball ~~21~~ made of a non-magnetic material and having embedded therein bar members ~~26 to 28~~ made of a magnetic material and arranged on three axes orthogonal to
10 | one another, a case ~~22~~ enclosing the ball ~~21~~ such that at least an upper portion of the ball ~~21~~ is exposed, magnetic members ~~31 to 34~~ fixed to the case ~~22~~ on two axes penetrating through the center of the ball ~~21~~ and orthogonal to each other so as to allow magnetic coupling to ends of the bar members, and ~~a~~ another magnetic
15 | member ~~35~~ fixed to the case ~~22~~ on an axis penetrating through the center of the ball ~~21~~ and orthogonal to the two axes so as to allow magnetic coupling to an end ~~28B~~ of one of the bar members ~~member~~ 28.
